

CSE12 - Lecture 2

Wednesday, April 3, 2024 10:00 AM

PA1 released today

Lecture 2

Test Driven Development - TDD
Write the tests first!!

- 1) Write method header
- 2) Write test cases
- 3) Write code
- 4) Fix code until all tests pass

```
public static int abs(int value) {  
    return 0;  
}
```

↑
default value

What is a test? What are we checking in the code?

↳ run your code
↳ check for errors → confidence code works
↳ check for correctness

JUnit is a simple framework to write repeatable tests.

Write a test for the absolute value method in the Math library: `int Math.abs(int value);`

```
assertEquals( 3, Math.abs(-3));  
assertNotEquals( -3, Math.abs(-3));  
if (true) {  
    fail("some error message");  
}
```

→ Fill in the blanks for `assertEquals` and `assertNotEquals`.

`assertEquals(expected, actual);`

primitive ==
objects .equals()

```
import static org.junit.Assert.assertEquals;  
import org.junit.Test;
```

```
public class TestJUnit {
```

```
    @Test  
    public void testQuestion1() {  
  
    }  
}
```

Command line:

```
javac -cp hamcrest-core-1.3.jar;junit-4.12.jar;. TestJava.java
```

```
java -cp hamcrest-core-1.3.jar;junit-4.12.jar;. org.junit.runner.JUnitCore TestJava
```

Or use Eclipse (IDE) *VS code*

↑
main method

What is `@Test` in the above code? What does it do?

JUnit annotation
↳ tells JUnit → this is a test

Name: _____ PID: _____ Code: 2959

sumNumbers

Given a string, return the sum of the numbers appearing in the string, ignoring all other characters. A number is a series of 1 or more digit chars in a row. (Note: Character.isDigit(char) tests if a char is one of the chars '0', '1', .. '9'. Integer.parseInt(string) converts a string to an int.)

sumNumbers("abc123xyz") → 123

sumNumbers("aa11b33") → 44

sumNumbers("7 11") → 18

What test cases should we write to confirm that our implementation works?

input (argument)	output (return value)
"abc123xyz"	123
"aa11b33"	44
"7 11"	18
" "	0
"	0
"	0
Null	0
"0b-1"	1
"3.14"	17

edge cases

evenOdd

Return an array that contains the exact same numbers as the given array, but rearranged so that all the even numbers come before all the odd numbers. Other than that, the numbers can be in any order. You may modify and return the given array, or make a new array.

evenOdd([1, 0, 1, 0, 0, 1, 1]) → [0, 0, 0, 1, 1, 1, 1]

evenOdd([3, 3, 2]) → [2, 3, 3]

evenOdd([2, 2, 2]) → [2, 2, 2]

What test cases should we write to confirm that our implementation works?

do Friday
